

# Incremental Learning for Object Detection on Embedded Systems using Machine Generated Bounding Boxes

Vittorio Mazzia

PhD Supervisors:

Marcello Chiaberge

Mario Roberto Casu

## Motivation and background

Training object class detectors typically requires large amount of data in which images are **manually annotated** with bounding boxes (bbox) for every instance of each class. This is particularly true for lightweight object class detectors that progressively improve their mean average precision ( $mAP$ ) increasing the number of examples available. The presented research suggests a methodology to exploit **generated data** from the field and a **collaboration** with multiple independent deep neural networks to obtain an increasingly more performing **embedded model** for the designated tasks.

## Materials and methods

- Dataset:** (OIDv4\_ToolKit)

	Apple	Grape	Lemon	Orange	Pear
Train	624	755	367	583	204
Validation	24	44	41	25	4
Test	57	124	79	95	27
Videos	5' 4"	12' 25"	34' 3"	7' 9"	9' 43"

- Hardware:**

- Tesla K80 (4992 Cuda Cores)

- Networks:**

- Faster R-CNN (with ROI-align)

- SSD (with Focal-Loss (1.1))

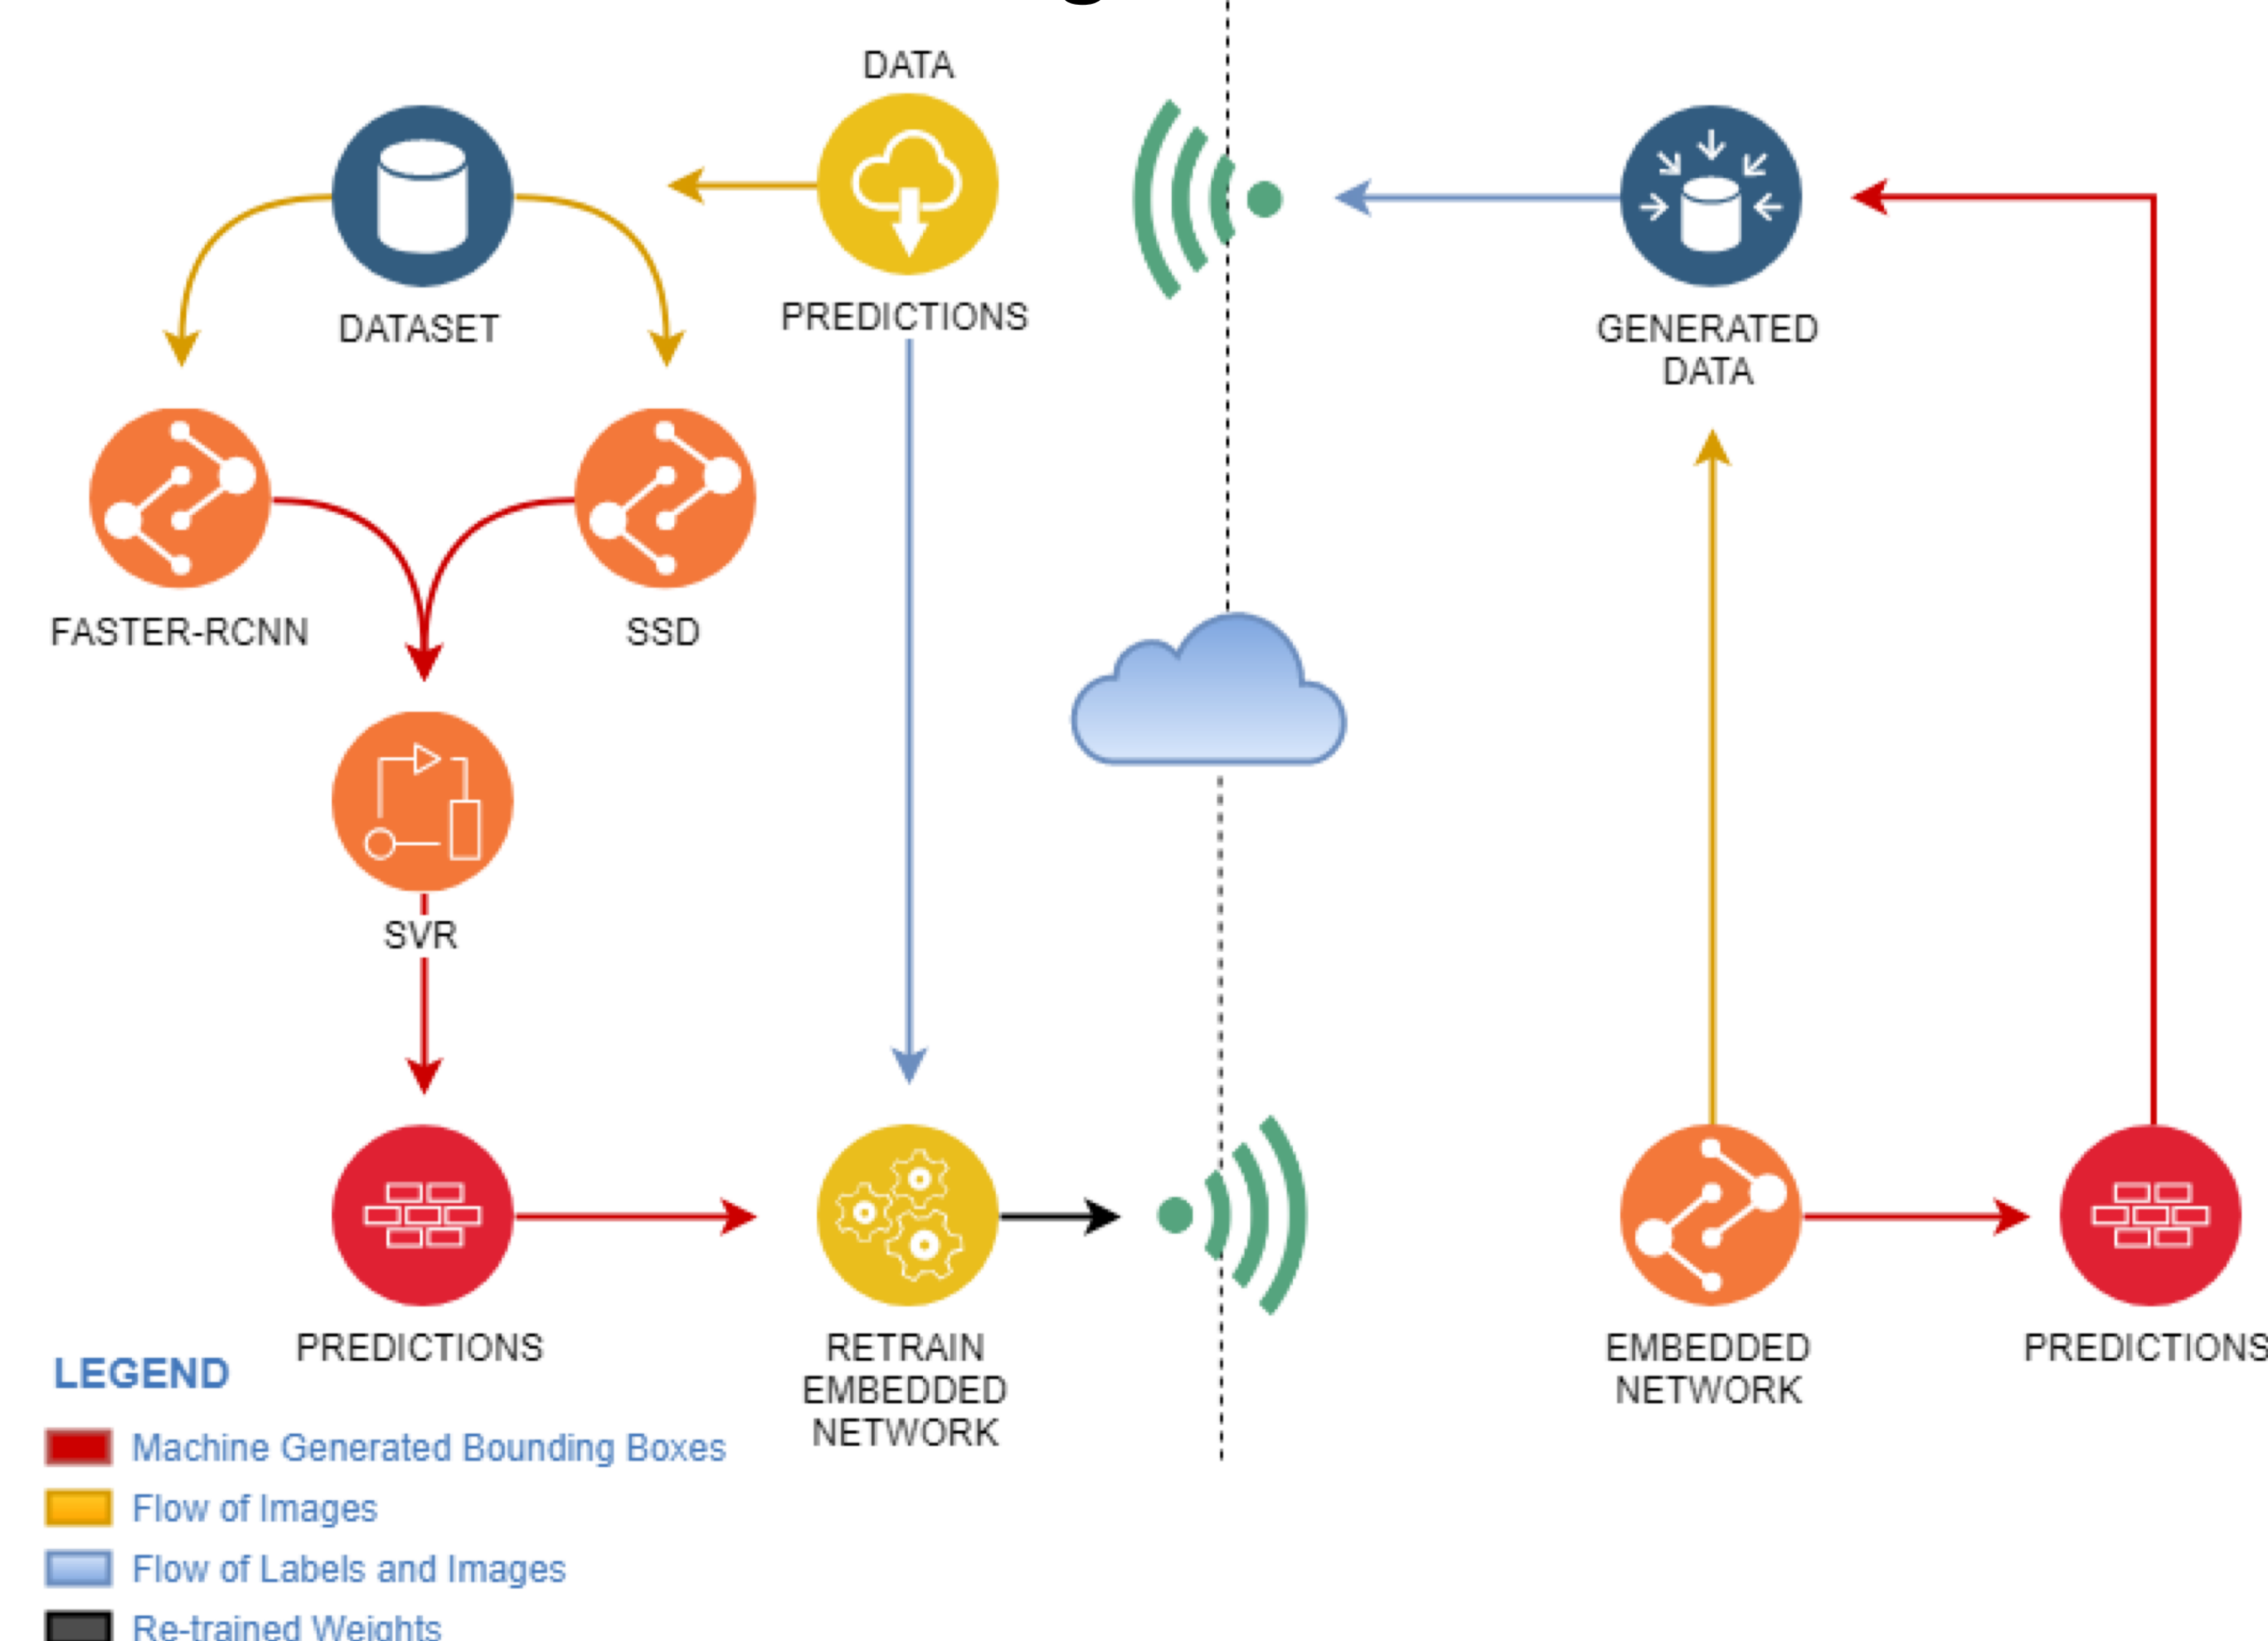

$$CE(p_t) = -\log(p_t) \quad (1)$$

$$FL(p_t) = -(1 - p_t)^\gamma \log(p_t) \quad (1.1)$$

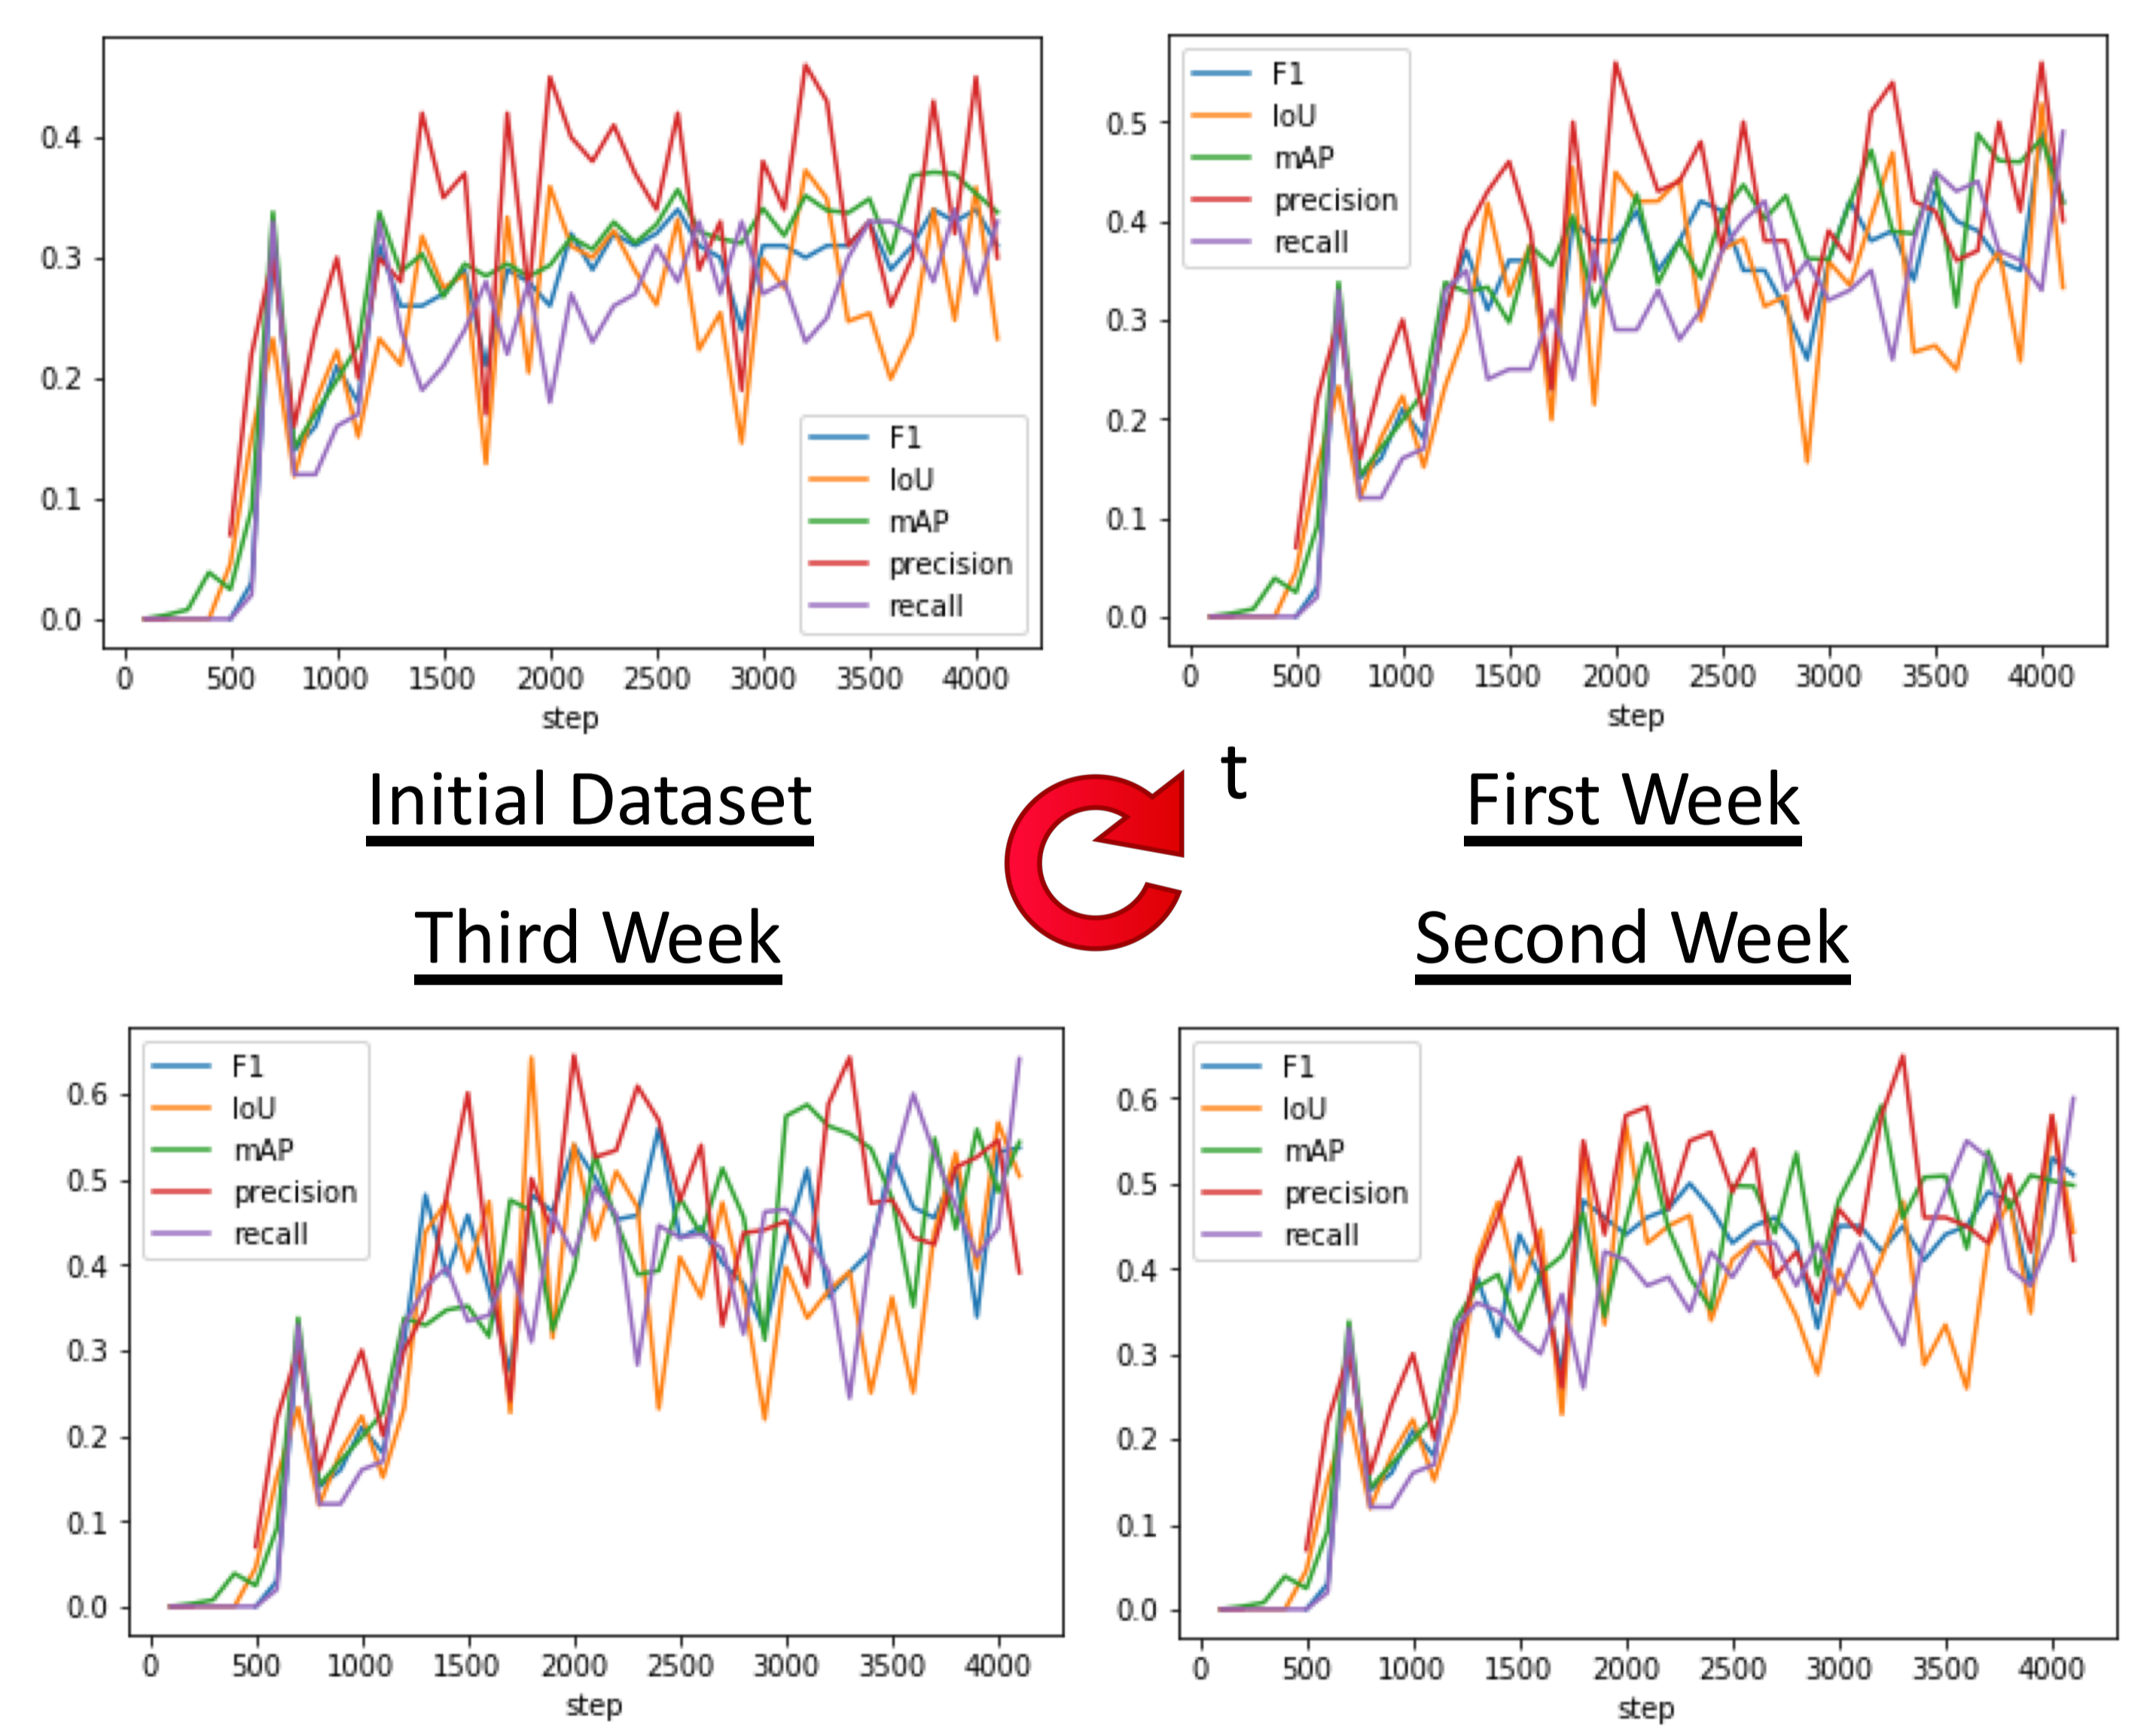

## Proposed Algorithm

A first architecture of the algorithm is shown in the graph at the bottom and it follows the following steps:

- An initial dataset is used to train a two-stage Faster-RCNN, a Single Shot Multibox Detector (SSD) and a **lightweight version** of it.
- Data generated by the embedded network (frames & predictions) is sent to the cloud.
- Received images are elaborated by the **ensemble network** that generates new bbox.
- New data are merged with the old one and, through a re-training, novel weights of the embedded SSD are generated

## Simulation Results

## Conclusions and future work

The methodology presented is the first of its kind and preliminary results have proven a remarkable effectiveness of the overall system. However, the proposed research requires further studies to improve the algorithm and assess its limitations and drawbacks.

- Substitute the SVR block with a FC layer that exploits backbone extracted features
- Look for saturation value of  $mAP$
